**Maximum Flow**

---

# The Maximum Flow Problem

## Given

- ▶ Directed graph  $G = (V, E)$
- ▶ A capacity function  $c: E \rightarrow \mathbb{R}^+$
- ▶ Two vertices  $s$  and  $t$ .

## $s, t$ -Flow

- ▶ Function  $f: E \rightarrow \mathbb{R}^+$  such that
- ▶  $f(e) \leq c(e)$ ,
- ▶ for all  $v \in V \setminus \{s, t\}$ ,  $\sum_{uv \in E} f(uv) = \sum_{vw \in E} f(vw)$ ,
- ▶  $\sum_{vs \in E} f(vs) = 0$ , and  $\sum_{tv \in E} f(tv) = 0$ .

The value  $|f|$  of an  $s, t$ -flow  $f$  is  $\sum_{sv \in E} f(s, v)$

# The Maximum Flow Problem

## Maximum Flow Problem

For a given directed graph and two given vertices  $s$  and  $t$ , find an  $s, t$ -flow  $f$  with maximum value.

## Multi-Source and Multi-Sink Flow

- ▶ Sources:  $s_1, s_2, \dots, s_k$
- ▶ Sinks:  $t_1, t_2, \dots, t_l$
- ▶ Add vertex  $s'$  and edges  $s's_i$  with  $c(s's_i) = \infty$  ( $1 \leq i \leq k$ ).
- ▶ Add vertex  $t'$  and edges  $(t_it')$  with  $c(t_it') = \infty$  ( $1 \leq i \leq l$ ).
- ▶ Find maximum  $s', t'$ -flow.

# Max Flow Algorithm

## "Naive" Approach

- ▶ Find some path  $P$  from  $s$  to  $t$  where each edge  $e$  has  $f(e) < c(e)$ .
- ▶ Add increase  $f(e)$  as much as possible for each edge of  $P$ .
- ▶ Repeat.

This approach will not always create an optimal solution

# Residual Graph

## Observation

- ▶ If  $f(uv) = k$ , we can assume there is an augmented edge  $vu$  with  $c(vu) \geq k$ , even if  $vu \notin E$ .

## Residual Graph $G_f = (V, E_f)$

- ▶  $E_f = \{ uv \mid uv \in E, f(uv) < c(uv) \} \cup \{ vu \mid uv \in E, f(uv) > 0 \}$
- ▶ 
$$c_f(uv) = \begin{cases} c(uv) - f(uv) & \text{if } uv \in E \\ f(vu) & \text{if } vu \in E \end{cases}$$

$f'$  is an  $s, t$ -flow for  $G_f$  if and only if  $f + f'$  is an  $s, t$ -flow for  $G$ .

# Ford-Fulkerson Algorithm

## Ford-Fulkerson Algorithm

- ▶ Start with  $f(e) = 0$  for all edges  $e \in E$ .
- ▶ Find a simple  $s, t$ -path  $P$  in  $G_f$ .
- ▶ Update  $f$  with maximum flow for  $P$ .
- ▶ Update  $G_f$ .
- ▶ Repeat.

What is the worst case runtime for this algorithm?

# Ford-Fulkerson Algorithm – Runtime

Consider the following case:

If the algorithm picks  $uv$  or  $vu$  in each iteration, it takes 2,000 iterations to find a maximum flow.

## Worst Case Runtime

- ▶ If  $c: E \rightarrow \mathbb{N}$ ,  $\mathcal{O}(m|f_{\max}|)$

# Edmonds-Karp Algorithm

## Edmonds-Karp Algorithm

- ▶ Start with  $f(e) = 0$  for all edges  $e \in E$ .
- ▶ Find a *shortest*  $s, t$ -path  $P$  in  $G_f$ .
- ▶ Update  $f$  with maximum flow for  $P$ .
- ▶ Update  $G_f$ .
- ▶ Repeat.

## Ford-Fulkerson

- ▶ Finds *some*  $s, t$ -path in  $G_f$ .
- ▶ Runtime:  $O(m|f_{\max}|)$  (integer capacities)

## Edmonds-Karp Algorithm

- ▶ Finds *a shortest*  $s, t$ -path in  $G_f$ .
- ▶ Runtime:  $O(nm^2)$

Best known result today:  $O(nm)$  (complicated)

---

## Max-Flow Min-Cut Theorem

---

## $s,t$ -Cut

An  $s,t$ -cut  $(S, T)$  in a graph  $G = (V, E)$  is a partition of  $V$  into  $S$  and  $T$  such that  $s \in S$  and  $t \in T$ .

The flow  $f(S, T)$  is defined as

$$f(S, T) = \sum_{x \in S, y \in T, xy \in E} f(xy) - \sum_{x \in S, y \in T, yx \in E} f(yx).$$

The capacity  $c(S, T)$  is defined as

$$c(S, T) = \sum_{x \in S, y \in T, xy \in E} c(xy).$$

## Lemma

Maximum  $s,t$ -flow  $\leq$  minimum  $s,t$ -cut, i. e.,  $\max_f |f| \leq \min_{(S,T)} c(S,T)$ .

*Proof.* Follows from definition. □

## Lemma

For each  $s,t$ -cut  $(S,T)$ ,  $f(S,T) = |f|$ .

*Proof.*

- ▶ Let  $V = \{s = v_0, v_1, v_2, \dots, v_{n-1}, v_n = t\}$  and  $V_i = \{v_i, v_{i+1}, \dots, v_n\}$ .
- ▶  $|f| = \sum_{sv \in E} f(s,v)$  and, for all  $v \in V \setminus \{s, t\}$ ,  $\sum_{uv \in E} f(uv) = \sum_{vw \in E} f(vw)$ .
- ▶ Thus,  $f(\{s\}, V_1) = f(\{s, v_1\}, V_2) = \dots = f(S, T)$ . □

# Max-Flow Min-Cut Theorem

## Theorem

For any  $s,t$ -flow  $f$ , the following three conditions are equivalent.

- (i)  $f$  is a maximum  $s,t$ -flow in  $G$ .
- (ii) There is no augmenting  $s,t$ -path in  $G_f$ .
- (iii) There is an  $s,t$ -cut  $(S, T)$  in  $G$  with  $c(S, T) = |f|$ .

(i)  $\rightarrow$  (ii): If there would be an  $s,t$ -path  $P$  in  $G_f$ ,  $|f|$  could be increased by the capacity of  $P$ .

(ii)  $\rightarrow$  (iii): There is no augmenting  $s,t$ -path in  $G_f$ . Let  $S$  be the set of vertices reachable from  $s$  in  $G_f$  and  $T = V \setminus S$ . If  $c(S, T) > f(S, T)$ , there is an edge  $xy$  in  $G_f$  with  $x \in S$  and  $y \in T$ . Thus,  $y$  is reachable from  $s$ . Contradiction.

(iii)  $\rightarrow$  (i): There is an  $s,t$ -cut  $(S, T)$  in  $G$  with  $c(S, T) = |f|$ . Because  $\max_f |f| \leq \min_{(S, T)} c(S, T)$ ,  $f$  is a maximum  $s,t$ -flow in  $G$ . □
